

MTX Bests Leflunomide in Polyarticular JRA

BY PATRICE WENDLING
Chicago Bureau

Methotrexate was more effective than leflunomide in the treatment of polyarticular juvenile rheumatoid arthritis, although both drugs resulted in high rates of clinical improvement in a multinational, randomized, controlled trial.

A total of 94 children, aged 3-17 years, with polyarticular juvenile rheumatoid arthritis (JRA) were randomized to either leflunomide (Arava) or methotrexate (MTX) for 16 weeks, followed by a 32-week blinded extension phase (N. Engl. J. Med. 2005;352:1655-66).

The dose of leflunomide was based on three weight categories: Patients weighing less than 20 kg received 100 mg of leflunomide for 1 day, followed by a maintenance dose of 10 mg every other day; 20 kg to 40 kg patients received 100 mg for 2 days, followed by 10 mg/day; and those weighing more than 40 kg received 100 mg for 3 days, followed by 20 mg/day. The MTX dose was

0.5 g/kg per week, with a maximum of 25 mg per week. Concomitant treatment with nonsteroidal anti-inflammatory drugs and prednisone was allowed.

At week 16, the rate of American College of Rheumatology Pediatric 30% (ACR Pedi 30) responses was significantly higher in the methotrexate group than in the leflunomide group (89% vs. 68%).

There was not a significant difference between the leflunomide and methotrexate groups in the other primary outcome

variable, the Percent Improvement Index (-44.41% vs. -52.87%).

In both groups, the improvements achieved at week 16 were maintained at week 48. The results compare favorably with previously published ACR Pedi 30 response rates of 48% with methotrexate, 44% with sulfasalazine, and 74% after 3 months of open-label etanercept, according to the authors.

"The higher-than-expected rates of responses in both treatment groups may in

part be attributed to the early stage of disease (median duration 4 months) in this population...," wrote lead author Earl Silverman, M.D., of the University of Toronto, a paid consultant for Sanofi-Aventis, which supported the study.

The most common adverse events in both groups included gastrointestinal symptoms, headache, and nasopharyngeal symptoms. ALT elevations were more frequent with MTX than with leflunomide during both phases of the study. ■

Kawasaki Disease Has No Ill Effect On Quality of Life

SAN DIEGO — Health-related quality of life in adolescents and young adults with Kawasaki disease is excellent regardless of coronary sequelae, according to results from a large cross-sectional study of Japanese patients presented at an international Kawasaki disease symposium.

Hiromi Muta, M.D., and his associates mailed a Medical Outcome Study Short Form 36 to 624 Japanese patients aged at least 16 years who had received a diagnosis of Kawasaki disease between 1973 and 1998 and were evaluated by coronary angiography or two-dimensional echocardiography at one of the study sites.

Of the 624 forms sent, 246 were completed and returned, said Dr. Muta of Kurume (Japan) University. Respondents ranged in age from 16 to 34 years. The investigators divided respondents into three groups: those with normal coronary measurements on angiography or echocardiography, those who had had aneurysms, and those who had experienced episodes of ischemia.

The investigators observed no differences in health-related quality of life among patients in all Kawasaki disease groups compared with the normal Japanese population after adjusting for age and gender, Dr. Muta said at the symposium, sponsored by the American Heart Association.

However, 29% of Kawasaki disease patients reported cigarette smoking and 12% were overweight, with a body mass index of 25 kg/m² or more, which only accelerates their risk of developing arteriosclerosis. "Long-term follow-up is necessary, since the risk of arteriosclerosis increases with age," he said.

Abbott Immunology and Abbott Bioresearch Center are devoted to the discovery and development of monoclonal antibodies. We are targeting IL-12, IL-18, and TNF- α , important mediators of autoimmune disorders:

- Psoriatic arthritis
- Psoriasis
- Ankylosing spondylitis
- Crohn's disease
