36

Colon Cancer Risk Rises With Low Vitamin D

S Major Finding: People with more than 75 nmol/L of circulating 25-hydroxyvitamin D (25-[OH]D) had a 40% lower risk of developing colorectal cancer 4 over a mean 3.8 years of follow-up, compared with those with less than 25 nmol/L >

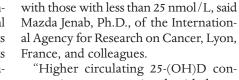

Data Source: A nested case-control investigation compared 1,248 participants in the EPIC study who developed first-incident colorectal cancer after enrollment and 1,248 healthy controls matched for age, sex, study center, menopausal status, and other characteristics.

Disclosures: The study was supported by a grant from the World Cancer Research Fund. None of the investigators reported having conflicts of interest.

BY LEANNE SULLIVAN

erum levels of vitamin D were inversely associated with colorectal cancer risk, according to findings from one of the first large investigations conducted in western European populations.

Participants with more than 75 nmol/L of circulating 25-hydroxy-vitamin D (25-[OH]D) had a 40% lower risk

centration was associated with lower colorectal risk in a dose-response manner," they reported (BMJ 2010 Jan. 10 [doi:10.1136/bmj.b5500]).

MICARDIS

(telmisartan) tablets 20.40.80 mg

WARNING: AVOID USE IN PREGNANCY When used in pregnancy, drugs that act directly on the renin-angiotensin system can cause injury and even death to the developing fetus. When pregnancy is detected, MICARDIS tablets should be discontinued as soon as possible. See Warnings and Precautions

BRIEF SUMMARY OF PRESCRIBING INFORMATION INDICATIONS AND USAGE

Hypertension

alone or in combination with other antihypertensive agen Cardiovascular Risk Reduction

stroke, or death from cardiovascular causes in patients 55 years of age or older at high risk of developing major cardiovascular events who are unable to take ACE inhibitors.

nary artery disease, peripheral arterial disease, stroke, transient ischemic attack, or high-risk diabetes (insulin-dependent or non-insulin depend-ent) with evidence of end-organ damage. MICARDIS can be used in addition to other needed treatment (such as antihypertensive, antiplatelet or lipid-lowering therapy).

Studies of telmisartan in this setting do not exclude that it may not preserve a meaningful fraction of the effect of the ACE inhibitor to which it was com-pared. Consider using the ACE inhibitor first, and, if it is stopped for cough only, consider re-trying the ACE inhibitor after the cough resolves.

Use of telmisartan with an ACE inhibitor is not recommended.

CONTRAINDICATIONS

WARNINGS AND PRECAD HONS Fetal/Neonatal Morbidity and Mortality Drugs that act directly on the renin-angiotensin system can cause fetal and neonatal morbidity and death when administered to pregnant women. Several dozen cases have been reported in the world literature in patients who were taking angiotensin converting enzyme inhibitors. When pregnancy is detected, discontinue MICARDIS tablets as soon as possible [see Boxed Warning]. The use of drugs that act directly on the renin-angiotensin system dur-

The use of drugs that act directly on the renin-angiotensin system dur-ing the second and third trimesters of pregnancy has been associated with fetal and neonatal injury, including hypotension, neonatal skull hypoplasia, anuria, reversible or irreversible renal failure, and death. Oligohydramnios has also been reported, presumably resulting from decreased fetal renal function; oligohydramnios in this setting has been associated with fetal limb contractures, craniofacial deformation, and hypoplastic lung development. Prematurity, intrauterine growth retarda-tion, and patent ductus arteriosus have also been reported, although it is pat degrupped to the concurrence word due to exposure to the drug. is not clear whether these occurrences were due to exposure to the drug. These adverse effects do not appear to have resulted from intrauterine drug exposure that has been limited to the first trimester. Inform moth-ers whose embryos and fetuses are exposed to an angiotensin II recep-tor antagonist only during the first trimester that most reports of fetal toxicity have been associated with second and third trimester exposure. Nonetheless, when patients become pregnant or are considering preg-nancy, have the patient discontinue the use of MICARDIS tablets as soon as possible. as possible.

Rarely (probably less often than once in every thousand pregnancies), no alternative to an angiotensin II receptor antagonist will be found. In these rare cases, the mothers should be apprised of the potential haz-ards to their fetuses, and serial ultrasound examinations should be per-formed to assess the intra-amniotic environment.

If oligohydramnios is observed, MICARDIS should be discontinued unless they are considered life-saving for the mother. Contraction stress testing (CST), a non-stress test (NST), or biophysical profiling (BPP) may be appropriate, depending upon the week of pregnancy. Patients and physicians should be aware, however, that oligohydramnios may not appear until after the fetus has sustained irreversible injury.

Infants with histories of *in utero* exposure to an angiotensin II receptor antagonist should be closely observed for hypotension, oliguria, and hyperkalemia. If oliguria occurs, attention should be directed toward sup-port of blood pressure and renal perfusion. Exchange transfusion or dialysis may be required as a means of reversing hypotension and/or substituting for disordered renal function.

Hypotension

In patients with an activated renin-angiotensin system, such as volumeand/or salt-depleted patients (e.g., those being treated with high doses of diuretics), symptomatic hypotension may occur after initiation of therapy with MICARDIS. Either correct this condition prior to administration reduced dose.

If hypotension does occur, the patient should be placed in the supine A transient hypotensive response is not a contraindication to further treat-ment, which usually can be continued without difficulty once the blood pressure has stabilized.

Hyperkalemia

Hyperkalemia Hyperkalemia may occur in patients on ARBs, particularly in patients with advanced renal impairment, heart failure, on renal replacement therapy, containing salt substitutes or other drugs that increase potassium evels. Consider periodic determinations of serum electrolytes to detect possible electrolyte imbalances, particularly in patients at risk.

Impaired Hepatic Function

As the majority of telmisartan is eliminated by biliary excretion, patients with biliary obstructive disorders or hepatic insufficiency can be expected to have reduced clearance. Initiate telmisartan at low doses and titrate slowly in these patients.

Impaired Renal Function

As a consequence of inhibiting the renin-angiotensin-aldosterone sys-tem, changes in renal function may be anticipated in susceptible indi-viduals. In patients whose renal function may depend on the activity of viduals. In patients whose renal function may depend on the activity of the renin-angiotensin-aldosterone system (e.g., patients with severe con-gestive heart failure or renal dysfunction), treatment with angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor antagonists has been associated with oliguria and/or progressive azotemia and (rarely) with acute renal failure and/or death. Similar results have been reported with MICARDIS.

In studies of ACE inhibitors in patients with unilateral or bilateral renal artery stenosis, increases in serum creatinine or blood urea nitrogen were observed. There has been no long term use of MICARDIS in patients with unilateral or bilateral renal artery stenosis but anticipate an effect similar to that seen with ACE inhibitors.

Dual Blockade of the Renin-Angiotensin-Aldosterone System

As a consequence of inhibiting the renin-angiotensin-Aldosterone sys-tem, changes in renal function (including acute renal failure) have been reported. Dual blockade of the renin-angiotensin-aldosterone system (e.g., by adding an ACE-inhibitor to an angiotensin II receptor antagonist) should include close monitoring of renal function.

The ONTARGET trial enrolled 25,620 patients ≥55 years old with atherthem to telmisartan only, ramipril only, or the combination, and followed them for a median of 56 months. Patients receiving the combination of MICARDIS and ramipril did not obtain any additional benefit compared to monotherapy, but experienced an increased incidence of renal dys-function (e.g., acute renal failure) compared with groups receiving telmis-artan alone or ramipril alone. Concomitant use of MICARDIS and ramipril is not recommended.

ADVERSE REACTIONS

The following adverse reaction is described elsewhere in labeling: Renal dysfunction upon use with ramipril.

Clinical Trials Experience

Because clinical studies are conducted under widely varying conditions, adverse reactions rates observed in the clinical studies of a drug cannot be directly compared to rates in the clinical studies of another drug and may not reflect the rates observed in practice.

Hypertension

MICARDIS has been evaluated for safety in more than 3700 patients, including 1900 treated for over six months and more than 1300 for over one year. Adverse experiences have generally been mild and transient in nature and have infrequently required discontinuation of therapy.

In placebo-controlled trials involving 1041 patients treated with various doses of MICARDIS (20-160 mg) monotherapy for up to 12 weeks, the overall incidence of adverse events was similar to that in patients treated with placebo.

Adverse events occurring at an incidence of $\geq 1\%$ in patients treated with MICARDIS and at a greater rate than in patients treated with placebo, irrespective of their causal association, are presented in Table 1.

Table 1 Adverse Events Occurring at an Incidence of \geq 1% in Patients Treated with MICARDIS and at a Greater Rate Than in Patients Treated with

	Telmisartan (n=1455) %	Placebo (n=380) %
Upper respiratory tract infection	7	6
Back pain	3	1
Sinusitis	3	2
Diarrhea	3	2
Pharyngitis	1	0

MICARDIS is indicated for the treatment of hypertension. It may be used

MICARDIS is indicated for reduction of the risk of myocardial infarction.

High risk for cardiovascular events can be evidenced by a history of coro-

None

WARNINGS AND PRECAUTIONS

The investigation "suggests that raising very low levels of 25-(OH)D to the mid-range may protect against colon cancer.'

The subjects were enrolled during 1992-1998 in the EPIC (European Prospective Investigation into Cancer and Nutrition) study, which includes 520,000 participants at 23 centers in 10 western European nations.

The nested case-control study looked at 1,248 participants in the EPIC study who developed first-incident colorectal cancer (CRC) after enrollment and 1,248 healthy controls matched for age,

sex, study center, menopausal status, and other characteristics.

Dr. Douglas K. Rex commented in an interview, "This is the largest study to address this issue, and the results were consistent across a range of European countries.

The authors called for prospective, randomized, controlled trials of vitamin D supplementation, but the results seem strong enough that patients interested in lowering their risk of CRC can be informed that higher blood levels of 25-(OH)D are associated with risk reduction." Dr. Rex is distinguished

professor of medicine at Indiana University, Indianapolis, and director of endoscopy at Indiana University Hospital.

At enrollment, the researchers measured prediagnostic 25-(OH)D levels using blood samples analyzed by enzyme immunoassay, and gauged dietary intake of vitamin D and calcium using questionnaires.

Using blood sample data in addition to dietary intake data accounted for endogenous vitamin D production from sun exposure.

Multivariate analysis controlled for

In addition to the adverse events in the table, the following events occurred at a rate of \geq 1% but were at least as frequent in the placebo group: influenza-like symptoms, dyspepsia, myalgia, urinary tract infection, abdominal pain, headache, dizziness, pain, fatigue, coughing, hypertension, chest pain, nausea, and peripheral edema. Discontinuation of therapy because of adverse events was required in 2.8% of 1455 patients treated with Micardis® (telmisartan) tablets and 6.1% of 380 placebo patients in placebo-controlled clinical trials.

The incidence of adverse events was not dose-related and did not correlate with gender, age, or race of patients.

The incidence of cough occurring with telmisartan in 6 placebo-controlled trials was identical to that noted for placebo-treated patients (1.6%).

In addition to those listed above, adverse events that occurred in more than 0.3% of 3500 patients treated with MICARDIS monotherapy in controlled or open trials are listed below. It cannot be determined whether these events were causally related to MICARDIS tablets:

Autonomic Nervous System: impotence, increased sweating, flushing; Body as a Whole: allergy, fever, leg pain, malaise; Cardiovascular: pal-pitation, dependent edema, angina pectoris, tachycardia, leg edema, abnormal ECG; CNS: insomnia, somnolence, migraine, vertigo, paresthesia, involuntary muscle contractions, hypoaesthesia; *Gastrointesti-nal*: flatulence, constipation, gastritis, vomiting, dry mouth, hemorrhoids, gastroenteritis, enteritis, gastroesophageal reflux, toothache, non-specific gastrointestinal disorders; *Metabolic*: gout, hypercholesterolemia, diabetes mellitus; *Musculoskeletal*: arthritis, arthralgia, leg cramps; *Psy-chiatric*: anxiety, depression, nervousness; *Resistance Mechanism*: infection, fungal infection, abscess, otitis media; *Respiratory*: asthma, bronchitis, rhinitis, dyspnea, epistaxis; *Skin*: dermatitis, rash, eczema, pruritus; Urinary: micturition frequency, cystitis; Vascular: cerebrovascular disorder; and Special Senses: abnormal vision, conjunctivitis, tinnitus, earache.

During initial clinical studies, a single case of angioedema was reported (among a total of 3781 patients treated).

Clinical Laboratory Findings In placebo-controlled clinical trials, clinically relevant changes in stan-dard laboratory test parameters were rarely associated with administration of MICARDIS tablets.

Hemoglobin: A greater than 2 g/dL decrease in hemoglobin was observed in 0.8% telmisartan patients compared with 0.3% placebo patients. No patients discontinued therapy due to anemia.

<u>Creatinine</u>: A 0.5 mg/dL rise or greater in creatinine was observed in 0.4% telmisartan patients compared with 0.3% placebo patients. One telmisartan-treated patient discontinued therapy due to increases in creatinine and blood urea nitrogen.

Liver Enzymes: Occasional elevations of liver chemistries occurred in higher frequency with placebo. No telmisartan-treated patients discon-tinued therapy due to abnormal hepatic function.

Cardiovascular Risk Reduction

Because common adverse reactions were well characterized in studies of telmisartan in hypertension, only adverse events leading to discontinor termisartan in hypertension, only adverse events leading to discontin-uation and serious adverse events were recorded in subsequent studies of telmisartan for cardiovascular risk reduction. In TRANSCEND (N=5926, 4 years and 8 months of follow-up), discontinuations for adverse events were 8.4% on telmisartan and 7.6% on placebo. The only serious adverse events at least 1% more common on telmisartan than placebo were intermittent claudication (7% vs 6%) and skin ulcer (3% vs 2%).

Postmarketing Experience The following adverse reactions have been identified during post-approval use of MICARDIS. Because these reactions are reported vol-untarily from a population of uncertain size, it is not always possible to

estimate reliably their frequency or establish a causal relationship to drug exposure. Decisions to include these reactions in labeling are typically based on one or more of the following factors: (1) seriousness of the reaction, (2) frequency of reporting, or (3) strength of causal connection to MICARDIS. The most frequently spontaneously reported events include: headache.

dizziness, asthenia, coughing, nausea, fatigue, weakness, edema, face edema, lower limb edema, angioneurotic edema, urticaria, hypersensi-tivity, sweating increased, erythema, chest pain, atrial fibrillation, con-gestive heart failure, myocardial infarction, blood pressure increased, gestive near failure, myocardial infarction, blood pressure increased, hypertension aggravated, hypotension (including postural hypotension), hyperkalemia, syncope, dyspepsia, diarrhea, pain, urinary tract infection, erectile dysfunction, back pain, abdominal pain, muscle cramps (includ-ing leg cramps), myalgia, bradycardia, eosinophilia, thrombocytopenia, uric acid increased, abnormal hepatic function/liver disorder, renal impair-ment including acute renal failure, anemia, increased CPK, anaphylactic reaction, and tendon pain (including tendonitis, tenosynovitis).

Rare cases of rhabdomyolysis have been reported in patients receiving angiotensin II receptor blockers, including MICARDIS.

DRUG INTERACTIONS

Digoxin: When MICARDIS was co-administered with digoxin, median increases in digoxin peak plasma concentration (49%) and in trough concentration (20%) were observed. Therefore, monitor digoxin levels when

initiating, adjusting, and discontinuing telmisartan for the purpose of keeping the digoxin level within the therapeutic range. Lithium: Reversible increases in serum lithium concentrations and toxicity have been reported during concomitant administration of lithium with angiotensin II receptor antagonists including MICARDIS. Therefore, monitor serum lithium levels during concomitant use.

Ramipril and Ramiprilat: Co-administration of telmisartan 80 mg once Ramipril and Ramiprilat: Co-administration of telmisartan 80 mg once daily and ramipril 10 mg once daily to healthy subjects increases steady-state C_{max} and AUC of ramipril 2.3- and 2.1-fold, respectively, and C_{max} and AUC of ramiprilat 2.4- and 1.5-fold, respectively. In contrast, C_{max} and AUC of telmisartan decrease by 31% and 16%, respectively. When co-administering telmisartan and ramipril, the response may be greater because of the possibly additive pharmacodynamic effects of the com-bined drugs, and also because of the increased exposure to ramipril and ramiprilat in the presence of telmisartan. Concomitant use of MICARDIS and ramipril is part ecompanded and ramipril is not recommended.

Other Drugs: Co-administration of telmisartan did not result in a clini-Other Drugs: Co-administration of telmisartan did not result in a clini-cally significant interaction with acetaminophen, amlodipine, glyburide, simvastatin, hydrochlorothiazide, warfarin, or ibuprofen. Telmisartan is not metabolized by the cytochrome P450 system and had no effects *in vitro* on cytochrome P450 enzymes, except for some inhibition of CYP2C19. Telmisartan is not expected to interact with drugs that inhibit cytochrome P450 enzymes; it is also not expected to interact with drugs metabolized by cytochrome P450 enzymes, except for possible inhibi-tion of the metabolism of drugs metabolized by CYP2C19.

USE IN SPECIFIC POPULATIONS

Pregnancy

Teratogenic Effects, Pregnancy Categories C (first trimester) and D (second and third trimesters). See Warnings and Precautions. **Nursing Mothers**

It is not known whether telmisartan is excreted in human milk, but telmisartan was shown to be present in the milk of lactating rats. Because of the potential for adverse effects on the nursing infant, decide whether to discontinue nursing or discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use

Safety and effectiveness in pediatric patients have not been established. **Geriatric Use**

Of the total number of patients receiving MICARDIS in hypertension clin-ical studies, 551 (19%) were 65 to 74 years of age and 130 (4%) were 75 years or older. No overall differences in effectiveness and safety were observed in these patients compared to younger patients and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

Of the total number of patients receiving MICARDIS in the cardiovascu-lar risk reduction study (ONTARGET), the percentage of patients ≥65 to <75 years of age was 42%; 15% of patients were ≥75 years old. No over-all differences in effectiveness and safety were observed in these patients compared to younger patients and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

Hepatic Insufficiency

Monitor carefully and uptitrate slowly in patients with biliary obstructive disorders or hepatic insufficiency.

OVERDOSAGE

Rx only

Limited data are available with regard to overdosage in humans. The most likely manifestation of overdosage with MICARDIS tablets would be hypotension, dizziness and tachycardia; bradycardia could occur from parasympathetic (vagal) stimulation. If symptomatic hypotension should occur, supportive treatment should be instituted. Telmisartan is not removed by hemodialysis.

Rev: November 2009

MC-BS (11-09) MC71754 possible confounders including body mass index, physical activity, smoking, education, and intake of fruits, vegetables, meats, and alcohol.

In addition, the investigation results were adjusted for season of blood collection.

The participants in this observational study had a mean age of 58 years, and about half were men. They were divided into five groups based on their circulating vitamin D levels: less than 25 nmol/L, 25-50 nmol/L, 50-75 nmol/L (reference group), 75-100 nmol/L, and more than 100 nmol/L.

The incidence ratio for colorectal cancer was 1.32 for those in the lowest quintile, compared with 0.77 for those in the highest, a statistically significant difference. Those in the second-lowest

The investigation 'suggests that raising very low levels of 25-(OH)D to the mid-range may protect against colon cancer.' However, the potential benefits of higher vitamin D levels should be balanced against having caution for the toxic potential and the risk of serious adverse events.

quintile had an incidence ratio of 1.29 for colorectal cancer.

The association between serum 25-(OH)D and disease was stronger for colon cancer (1.90 vs. 0.71 for the lowest and highest quintiles, respectively) than for rectal cancer (0.77 vs. 0.82).

When the analysis was restricted to dietary intake, however, the researchers found that "higher consumption of dietary calcium, but not dietary vitamin D, was found to be associated with a reduced risk." Participants with the lowest levels of dietary calcium had an incidence rate of 1.33, versus 0.95 in those with the highest dietary intake of calcium.

In addition, alcohol intake appeared to be a risk factor, as "the highest colorectal cancer risk was seen in those with the lowest circulating levels of 25-(OH)D and the highest level of alcohol consumption," with an incidence rate of 1.46, compared with 0.82 in the group with the highest level of vitamin D and lowest alcohol intake.

One limitation of the study was the short follow-up time. "However, exclusion of cases with less than 2 years of follow-up did not alter any of the findings," the researchers said.

Randomized trials are needed to "determine whether vitamin D has a causal role in colorectal cancer prevention or whether it is a marker of other events" before recommending vitamin D supplementation for this purpose, the authors noted.

"The potential cancer risk benefits of higher vitamin D levels should be balanced" against having caution for the toxic potential and the risk of serious adverse events, they added.
