The following events occurred in ≤1% but >0.1% of patients treated with amlodipine in controlled clinical trials or under conditions of open trials or marketing experience where a causal relationship is uncertain; they are listed to alert the physician to a possible relationship: Cardiovascular: arrhythmia (including ventricular tachycardia and atrial fibrillation), bradycardia, chest pain, hypotension, peripheral ischemia, syncope, tachycardia, postural dizziness, postural hypotension, bradycardia, chest pain, hypotension, peripheral ischemia, syncope, tachycardia, postural dizziness, postural hypotension, vasculitis. Central and Peripheral Nervous System: hypoesthesia, neuropathy peripheral, paresthesia, tremor, vertigo. Gastrointestinal: anorexia, constipation, dyspepsia, **dysphagia, diarrhea, flatulence, pancreatitis, vomiting, gingival hyperplasia. General: allergic reaction, asthenia, ** back pain, hot flushes, malaise, pain, rigors, weight gain, weight decrease. Musculoskeletal System: arthralgia, arthrosis, muscle cramps, ** myalgia. Psychiatric: sexual dysfunction (male ** and female), insomnia, nervousness, depression, abnormal dreams, anxiety, depersonalization. Respiratory System: dyspona.** epistaxis. Skin and Appendages: angioedema, erythema multiforme, pruritius, ** rash, ** rash erythematous, rash maculopapular. Special Senses: abnormal vision, conjunctivitis, diplopia, eye pain, tinnitus. Urinary System: micturition frequency, micturition disorder, nocturia. Autonomic Nervous System: dry mount, sweating increased. Metabolic and Nutritional: hyperplycemia, thirst. Hemopoletic: leukopenia, purpura, thrombocytopenia. The following events occurred in ≤0.1% of patients treated with amlodipine in controlled clinical trials or under conditions of open trials or marketing experience: cardiac failure, pulse irrequality, extrasystoles, skin discoloration, urticaria, skin dryness, alopecia, cermatitis, muscle weakness, twitching, ataxia, hype

Anglo-Scandinavian Cardiac Outcomes Trial (ASCOT): In ASCOT involving 10,305 participants treated with atorvastatin 10 mg daily (n=5,188) or placebo (n=5,137), the safety and tolerability profile of the group treated with atorvastatin was comparable to that of the group treated with placebo during a median of 3.3 years of follow-up. The following adverse events were reported, regardless of causality assessment, in patients treated with atorvastatin in clinical trials. The events in italics occurred in ≥2% of patients and the events in plain type occurred in 2% of patients. Body as a Whole: Chest pain, face edema, Fevr, neck rigidity, malaise, photosensitivity reaction, generalized edema. Digestive System: Nausea, gastroenteritis, liver function tests abnormal, colitis, vomiting, gastritis, dry mouth, rectal hemorrhage, esophagitis, eructation, glossitis, mouth ulceration, anorexia, increased appetite, stomatitis, biliary pain, chellitis, cholestatic jaundice. Respiratory System: Bronchitis, rhinitis, pneumonia, dyspnea, asthma, epistaxis. Nervous System: Insomnia, dizziness, paresthesia, somnolence, amnesia, abnormal dreams, libido decreased, emotional lability, incoordination, peripheral neuropathy, torticollis, facial paralysis, hyperkinesia, depression, hypesthesia, hypertonia. Musculoskeletal System: Arribritis, leg cramps, bursitis, tenosynovitis, myasthenia, tendinous contracture, myositis. Skin and Appendages: Pruritus, contact dermatitis, breast enlargement, metrorrhagia, nephritis, urinary incontinence, urinary retention, urinary urigenov, abnormal ejaculation, uterine hemorrhage. Special Senses: Amblyopia, tinnitus, dry eyes, refraction disorder, eye hemorrhage, deafness, glaucoma, parosmia, taste loss, taste perversion. Cardiovascular System: Palpitation, vasodilatation, syncope, migraine, postural hypotension, phlebitis, angioneurotic edema, buperglycemia, creatine phosphokinase increased, gout, weight gain, hypoglycemia. Hemic and Lymphatic System: Ecchymosis, anemia

safety and tolerability profile of atorvastatin 10 to 20 mg daily was generally similar to that of placebo (see **PRECAUTIONS**, **Pediatric Use**). **OVERDOSAGE**: There is no information on overdosage with CADUET in humans. **Information on Amlodipine**: Single oral doses of amlodipine maleate equivalent to 4 or more mg amlodipine/kg in mice and rats, respectively, caused deaths. Single oral amlodipine maleate doses equivalent to 4 or more mg amlodipine/kg in dogs (11 or more times the maximum recommended clinical dose on a mg/m² basis) caused a marked peripheral vasodilation and hypotension. Overdosage might be expected to cause excessive peripheral vasodilation with marked hypotension and possibly a reflex tachycardia. In humans, experience with intentional overdosage of amlodipine is limited. Reports of intentional overdosage include a patient who ingested 250 mg and was asymptomatic and was not hospitalized and had hypotension (90/50 mmHg) which normalized following plasma expansion. A patient who took 70 mg amlodipine and an unknown quantity of benzodiazepine plasma concentration. A case of accidental drug overdose has been documented in a 19-month-old male who ingested 30 mg amlodipine (about 2 mg/kg). During the emergency room presentation, vital signs were stable with no evidence of hypotension, but a heart rate of 180 bpm. Ipecaer 3.5 hours after ingestion and on subsequent observation (overnight) no sequelae were noted. If massive overdose should occur, active cardiac and respiratory monitoring should be instituted. Frequent blood pressure measurements are essential. Should hypotension occur, cardiovascular support including elevation of the extremities and the judicious administration of the benefit. **Information on Atorvastatin**: There is no specific treatment for atorvastatin overdosage. In the event of an overdose, the patient should be instituted symptomatically, and supportive measures instituted as required. Due to extensive drug binding to plasma proteins, hemodialysis is not expected to significan

Based on patient weight of 50 kg.

*These events occurred in less than 1% in placebo-controlled trials, but the incidence of these side effects was between 1% and 2% in all multiple dose studies.

Cognition Improved by **Carotid Artery Stenting**

Faster cognition after stenting is related to improved blood perfusion to the brain, imaging study suggests.

BY BRUCE K. DIXON Chicago Bureau

CHICAGO — Carotid artery stenting appeared to improve cognitive function based on the results of what investigators said is the first study to look at perfusion and diffusion-weighted imaging before and after stenting.

"We found that stenting of the carotid artery significantly increased cognitive speed," Dr. Iris Grunwald said at the Radiological Society of North America annual meeting. Studies of brain function following carotid endarterectomy have produced mixed results, and there is no consensus in the literature as to whether carotid intervention improves cognition.

stenosis.' Dr. Grunwald and her colleagues at the Saarland University Clinic in Homburg, performed carotid artery stenting on 29 patients. Mean age was 68 years and mean degree of stenosis was 90%. People were excluded from the study if they had paresis in the upper extremity, impairment in eyesight, and/or hemianopsia. Those with psychiatric disease or insufficient command of language also were excluded.

Stents were placed in the left carotid in 18 patients. All of the patients were asymp-

tomatic and right handed. Therefore, speech-related functions were primarily left-brain functions in these patients, she explained.

Perfusion and diffusion-weighted magnetic resonance imaging was performed 24 hours before and 48 hours after intervention (see images). All patients were tested using the Mini-Mental State Examination (MMSE) and symbol digit test and subtests of the CERAD battery. Cognitive speed was assessed with the modified trail making test (ZVT) and the Stroop colored word test.

Findings from the Beck Depression Inventory showed that none of the patients suffered from depression. Mean improvements in cognitive speed ranged from 3% on the ZVT number connection test to almost 7% on the Stroop colored word test.

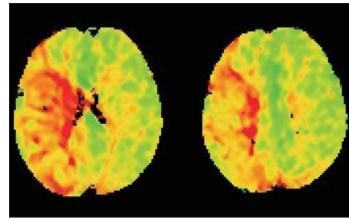

"Stenting of the internal carotid artery seems to improve functions that involve cognitive speed, regardless of the patient's age, the side of stenosis, or the de-

gree of stenosis," Dr. Grunwald said. "Some patients showed [more] improvement after stent placement than others. The higher the degree of stenosis, the more marked was the perfusion deficit.

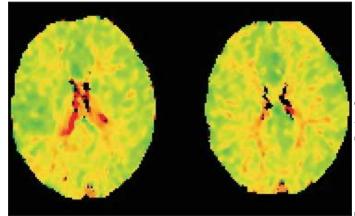

Post-stenting perfusion increased in 17 of the 18 patients, though in 9 of them the increase was described as "slight." Increased brain perfusion correlated with increased memory function but did not quite reach sta-

tistical significance.

"Perfusion of the brain may be what improves cognitive function," Dr. Grunwald said in an interview. "If that's the case, other means may be taken to improve blood flow. For example, we are also doing studies with sildenafil, which can also improve blood perfusion in the brain and, it appears, improve cognitive functioning afterwards. Further studies with different time intervals and more refined testing are needed to confirm our findings.

Perfusion and diffusion-weighted MRIs show impaired cerebral blood flow (red) in a carotid stenosis patient.

Carotid stent placement in the same patient restored cerebral blood flow to closer-to-normal (green) levels.
