BRIEF SUMMARY For Intravenous In DESCRIPTION

ADENOSCAN

STORE FLOW Sine is an endogenous nucleoside occurring in all cells of the body. It is chemically 6-amino-9-beta-D-ribofuranosyl-9-H-purine. Sine is a white crystalline powder. It is soluble in water and practically insoluble in alcohol. Solubility increases by warming and lowering the pH of lution.

Each Adenoscan vial contains a sterile, non-pyrogenic solution of adenosine 3 mg/mL and sodium chloride 9 mg/mL in Water for Injection, q.s. The pH of the solution is between 4.5 and 7.5.

INDICATIONS AND USAGE:

can is indicated as an adjunct to thallium-201 myocardial perfusion scintigraphy in patients unable to exercise adequately (See WARNINGS).

CONTRAINDICATIONS:

- us Adenoscan should not be administered to individuals with
 - 1. Second- or third-degree AV block (except in patients with a functioning artificial pacemaker).
- Sinus node disease, such as sick sinus syndrome or symptomatic bradycardia (except in patients with a functioning artificial pacemaker).
 Known or suspected bronchoconstrictive or bronchospastic lung disease (e.g., asthma).
 Known hypersensitivity to adenosine.

WARNINGS: Fatal Cardiac Arrest, Life Threatening Ventricular Arrhythmias, and Myocardial Infarction. Fatal cardiac arrest, sustained ventricular tachycardia (requiring resuscitation), and nonfatal myocardial infarction have been reported coincident with Adenoscan infusion. Patients with unstable angina may be at greater risk. Appropriate resuscitative measures should be available.

Adendscan infusion. Patients with unstable angina may be at greater risk. Appropriate resuscicative measures shown we evanave. Sinoatrial and Atrioventricular Nodal Block Adenoscan everts a direct depressant effect on the SA and AV nodes and has the potential to cause first, second- or third-degree AV block, or sinus bradycardia. Approximately 6.3% of patients develop AV block with Adenoscan, including first-degree (2.9%), second-degree (2.6%) and third-degree (0.8%) heart block. All episodes of AV block have been asymptomatic, transient, and did not require intervention. Adenoscan cause sinus bradycardia. Adenoscan should be used with caution in patients with pre-existing first-degree AV block to block and build be avoided in patients with high-grade AV block or sinus node dysfunction (except in patients with a functioning artificial pacemaker). Adenoscan should be discontinued in any patient who develops persistent or symptomatic high-grade AV block. Sinus pause has been rarely observed with adenosine influsions.

Hypotension Adenoscan is a potent peripheral vasodilator and can cause significant hypotension. Patients with an intact baroreceptor reflux mechanism are i maintain blood pressure and tissue perfusion in response to Adenoscan by increasing heart rate and cardiac output. However, Adenoscan should b with caution in patients with autonomic dysfunction, stenotic valvular heart disease, pericarditis or pericardial effusions, stenotic carotid artery disea cerebrovascular insufficiency, or uncorrected hypovolemia, due to the risk of hypotensive complications in these patients. Adenoscan should be discor in any patient who develops persistent or symptomatic hypotension.

Hypertension Increases in systolic and diastolic pressure have been observed (as great as 140 mm Hg systolic in one case) concomitant with Adenoscan infusion; most increases resolved spontaneously within several minutes, but in some cases, hypertension lasted for several hours.

onstriction is a respiratory stimulant (probably through activation of carotid body chemoreceptors) and intravenous administration in man has no increase minute ventilation (Ve) and reduce arterial PCO2 causing respiratory alkalosis. Approximately 28% of patients experi-nlessness (dyspnea) or an urge to breathe deeply with Adenoscan. These respiratory complaints are transient and only rarely require

intervention. Adenosine administered by inhalation has been reported to cause bronchoconstriction in asthmatic patients, presumably due to mast cell degranulation and histamine release. These effects have not been observed in normal subjects. Adenoscan has been administered to a limited number of patients with asthma and mild to moderate exacerbation of their symptoms has been apported. Respiratory componise has occurred during adenosine indusion in patients with obstructive pulmonary disease. Adenoscan should be used with caution in patients with obstructive lung disease not associated with bronchoconstriction (e.g., enphysema, bronchitis, etc.) and should be avoided in patients with bronchoconstriction or bronchospasm (e.g., asthma). Adenoscan should be discontinued in any patient who develops severe respiratory difficulties.

PRECAUTIONS:

Drug Interactions
Intravenous Adenoscan has been given with other cardioactive drugs (such as beta adrenergic blocking agents, cardiac glycosides, and calcium
channel blockers) without apparent adverse interactions, but its effectiveness with these agents has not been systematically evaluated. Because
of the potential for additive or synergistic depressant effects on the SA and AV nodes, however, Adenoscan should be used with caution in the
presence of these agents. The vasoactive effects of Adenoscan are inhibited by adenosine receptor antagonists, such as methylynathnise (e.g.,
caffeine and theophyline). The safety and efficacy of Adenoscan are inhibited by adenosine receptor antagonists, such as methylynathnise (e.g.,
caffeine ad theophyline). The safety and efficacy of Adenoscan in the presence of these agents has not been systematically evaluated. The
vasoactive effects of Adenoscan are potentiated by nucleoside transport inhibitors, such as dipyridamole. The safety and efficacy of Adenoscan
in the presence of diperdamole has not been systematically evaluated. Whenever possible, drugs that might inhibit or augment the effects of
adenosine should be withheld for at least five half-lives prior to the use of Adenoscan.

Carcinogenesis, Mutagenesis, Impairment of Fertility Studies in animals have not been performed to evaluate the carcinogenic potential of Adenoscan. Adenosine was negative for genotoxic potential in the Salmonella (Ames Test) and Mamalian Microsome Assav. Adenosine, however, like other nucleosides at millimolar concentrations present for several doubling times of cells in culture, is known to produce a variety of chromosomal alterations. Fertility studies in animals have not been conducted with adenosine.

Pregnancy Category C Animal reproduction studies have not been conducted with adenosine; nor have studies been performed in pregnant women. Because it is not known whether Adenoscan can cause fetal harm when administered to pregnant women, Adenoscan should be used during pregnancy only if clearly needed. Pediatric Use The safety and effectiveness of Adenoscan in patients less than 18 years of age have not been established.

Geriatric Use Clinical studies of Adenoscan did not include sufficient numbers of subjects aged younger than 65 years to determine whether they respond differently. Other reported experience has not revealed clinically relevant differences of the response of elderly in comparison to younger patients. Greater sensitivity of some older individuals, however, cannot be ruled out.

VERSE REACTIONS: Infolwing reactions with an incidence of at least 1% were reported with intravenous Adenoscan among 1421 patients enrolled in controlled and uncontrolled .clinical traits. Despite the short half-life of adenosine, 10.0% of the side effects occurred not with the infusion of Adenoscan but several hours after the sign terminated. Also, 8.4% of the side effects that began coincident with the infusion of up to 24 hours after the infusion was complete. In ny cases, it is not possible to know whether these late adverse events are the result of Adenoscan infusion.

Flushing Chest discomfort Dyspnea or urge to breathe deeply Headache Throat, neck or iaw discomfort	44% 40% 28% 18% 15%	Lightheadedness/dizziness Upper extremity discomfort ST segment depression First-degree AV block Second-degree AV block	12% 4% 3% 3% 3%	Hypotension Nervousness Arrhythmias	2% 2% 1%
Gastrointestinal discomfort	13%	Paresthesia	2%		
Adverse experiences of any severity reported in less than 1% of patients include:					
Body as a Whole: back discomfort; lower extremity discomfort; weakness.					
Cardiovascular System: nonfatal myocardial infarction; life-threatening ventricular arrhythmia; third-degree AV block; bradycardia; palpitation; sinus exit block; sinus pause; sweating; Twave changes, hypertension (systolic blood pressure > 200 mm Hg).					

Central Nervous System: drowsiness; emotional instability; tremors. Genital/Urinary System: vaginal pressure: urgency.

torv System: cough

Special Senses: blurred vision: dry mouth: ear discomfort: metallic taste: nasal congestion: scotomas: tongue discomfort

OVERDOSAGE:

OVERDOSAGE: The half-life of adenosine is less than 10 seconds and side effects of Adenoscan (when they occur) usually resolve quickly when the infusion is discontinued, although delayed or persistent effects have been observed. Methylxanthines, such as caffeine and theophylline, are competitive adenosine receptor antagonists and theophylline has been used to effectively terminate persistent side effects. In controlled U.S. clinical trial: theophylline (50-125 mg slow intravenous injection) was needed to abort Adenoscan side effects in less than 2% of patients. d theophylline, are competitive . In controlled U.S. clinical trials,

theophylline (50-125 mg slow intravenous injection) was needed to abort Adenoscan side effects in less than 2% of patients. **DOSAGE AND ADMINISTRATION:** For intravenous infusion only. Adenoscan should be given as a continuous peripheral intravenous infusion. The recommended intravenous does for adults is 140 mcg/kg/min infused for six minutes (total does of 0.84 mg/kg). The required does of thallium-201 should be injected at the midpoint of the Adenoscan infusion (i.e., after the first three minutes of Adenoscan). Thalium-201 is physically compatible with Adenoscan and may be injected directly into the Adenoscan infusion set. The injection should be as close cases as possible to prevent an indevrent increase in the does of Adenoscan (the contents of the V tubing) being administered. There are no data on the safety or efficacy of alternative Adenoscan infusion protocols. The order and officance of Advencement during the total contents on the safety or efficacy of alternative Adenoscan infusion protocols.

Note: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration

47101/Revised: April 2005

DX DERM

5-year-old Hispanic girl presented with an 18-month history of nonhealing, slightly painful, firm, 1- to 4-cm plaques on her left arm, and a sinus draining serosanguineous fluid. She had been living in Mexico at the time of onset and had no history of trauma, fever, cough, or weight loss. What's your diagnosis?

SAN DIEGO — Differential diagnoses included cutaneous tuberculosis, mycetoma, leishmaniasis, botryomycosis, coccidioidomycosis, osteomyelitis, bone and soft tissue tumors, and other deep fungal or atypical mycobacterial infections.

Diagnostic tests—including complete blood count, chemistry panel, and xrays of the chest and left arm-were all negative.

Skin biopsy revealed a suppurative granuloma with deeply basophilic granules in the dermis. Gram stain revealed gram-positive branched bacteria. Culture was diagnostic for actinomycetoma, as it grew Nocardia brasiliensis, Dr. Justine Hyoju Yun said at the annual meeting of the Society for Pediatric Dermatology.

First-line treatment for actinomycetoma is 5-10 mg/kg per day of trimethoprim and 25-50 mg/kg per day of sulfamethoxazole in two to four divided dosages. Immunocompetent patients should be treated for 3 months, and immunocompromised patients should be treated for 6 months.

Dr. Yun's patient was started on 160 mg oral trimethoprim and 800 mg oral sulfamethoxazole daily in two divided doses for 3 months. She has responded well to treatment, with residual atrophic pink plaques on physical exam.

Mycetoma is a chronic, granuloma-

tous infection of the skin and subcutaneous tissues caused by either bacteria or fungi. Untreated, it can spread locally to adjacent muscle and bone.

Firm, painless nodules usually appear on the foot, but also may affect the hands, arms, chest, and buttocks. Tubercles and draining sinuses may develop, as well as ulceration and scarring.

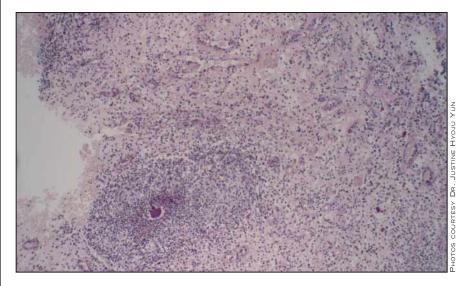

Actinomycetoma is caused by actinomycetes, whereas eumycetoma is caused by fungi. They are clinically indistinguishable but are treated differently. Causative microorganisms include the Actinomadura species, Nocardia species, and Streptomyces species. N. brasiliensis is implicated in 98% of cases in Mexico, said Dr. Yun, a dermatology resident at King/Drew Medical Center, Los Angeles.

In the West, mycetoma is most common in Mexico, followed by Venezuela and Argentina. It affects males more often than females (5:1).

Left untreated, mycetoma can spread locally from skin to subcutaneous fascia and bone.

Culture and biochemical testing are necessary to identify the causative agent, as this determines treatment. However, Nocardia species are difficult to culture and can take up to 3 weeks to grow.

-Doug Brunk

The safety and efficacy of Adenoscan administered by the intracoronary route have not been established
